

# European Studbook for Forest Reindeer, *Rangifer tarandus fennicus*, 2018

Leif Blomqvist

NORDENS  
ARK

The mission of the European studbook programme is to establish a healthy *ex situ* population of forest reindeer in Europe by promoting the use of good management practices and to maintain a sustainable, cooperatively managed stock that can contribute to reintroductions and re-stockings in the wild.

## 1. Introduction

Finland is the only EU country with a wild population of reindeer. In the past, Eurasian forest reindeer (*Rangifer tarandus fennicus*) were widespread in most parts of the country but due to extensive hunting the population crashed and the wild forest reindeer became extinct in the early 1900s. Fortunately wild populations survived in the western parts of the former Soviet Union and after World War II, the subspecies slowly started to re-colonize Finland with the first births observed in the 1950s (Heikura *et al.* 1985). During the following decades, forest reindeer numbers started to grow and by the early 1980s, roughly 500 animals were living in the border zones of eastern Finland. From being extinct for almost half a century, forest reindeer had through natural dispersal returned to the country.

## 2. Reintroductions carried out in the 1980s

Stochastic events make isolated populations more vulnerable to extinction than animals with a widespread distribution. Because of the limited Finnish distribution obvious risks existed that a potential epidemic could wipe out the entire population. To avoid another eradication, two males and eight females, six of which were pregnant, were caught in 1979-1980 and transferred to an on-site enclosure in the Suomenselkä area in central Finland where breeding was conducted for five years before the animals were released in Salamajärvi National Park in the early 1980s (Kojola 1982; Kojola 1993; Bisi & Härkönen 2007; Hulkko 2011; Blomqvist & Richardson 2012). A second backup population was later established in the Karstula-Ähtäri area in central Finland, where three males and fourteen females were released from the zoo in Ähtäri from 1988-1994 (Blomqvist 2008).

## 3. *In situ* population status in the EU

The Finnish subpopulations have been monitored regularly through aerial censuses. The eastern population in Kainuu expanded to 900 animals in the mid-1990s, while the reintroduced stock in Suomenselkä increased to 250 head. A peak was reached in the early 21st century when the total number of animals in the country was put close to 2.500 head (Blomqvist 2015). After 2003 the expansion, however, levelled off at around 1.500 individuals in Suomenselkä, while the eastern subpopulation has decreased by 10% per year and stagnated to the same size as in the early 1980s (Figure 1). The reintroduced population in Karstula-Ähtäri has never taken root, and the past two years' surveys reveal that it has stagnated at a level of not more than 20-30 animals. The current stronghold therefore lies in central Finland where the winter survey in 2018 estimated the population at 1.500 animals, 18% of which were calves, while corresponding numbers for the eastern subpopulation simultaneously revealed some 750 animals, with 11% calves. The population assessment for Finland was consequently estimated at around 2.250 animals in 2018 (Figure 1).

Although the decline in Kainuu appears to have levelled off, its meagre size makes it henceforth vulnerable to stochastic events including increased predation, diseases, traffic accidents and climate warming. The reintroduced subpopulation in the central part of the country has moved northwards over the last few years and is expected to increase in number (Paasivaara *et al.* 2018). Currently forest reindeer are classified as *Near Threatened* in the Finnish Red Data Book (2019) and listed in Annex II of the EU Habitat Directive where it is assessed as “unfavourable-inadequate” in Article 17.

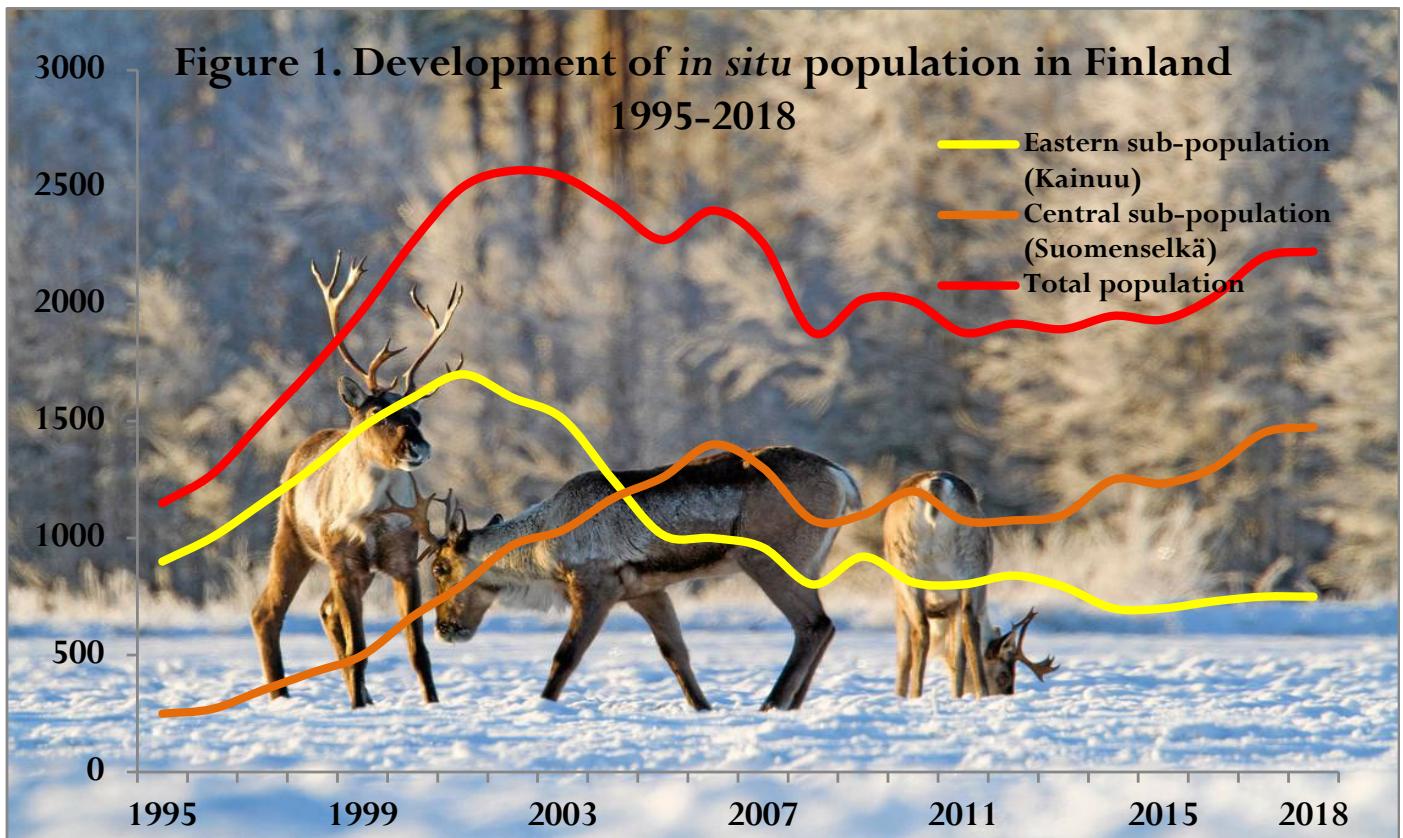

Figure 1. Development of in situ population in Finland 1995-2018

#### 4. Reasons for decline

Forest reindeer have a low reproductive rate and unlike the other deer species in Finland, moose (*Alces alces*), white-tailed deer (*Odocoileus virginianus*) and roe deer (*Capreolus capreolus*), forest reindeer give birth to only a single calf at a time. If mortality starts to rise, growth can end abruptly and turn into a decline.

##### 4.1. Landscape changes

Like the North American woodland caribou (*Rangifer t. caribou*), the Eurasian subspecies is sensitive to human-induced changes that have taken place in the boreal forest over recent decades. Marshes have been drained, forests cut down, power lines built, and road networks extended into large areas of previously untouched forests. Intensified forestry has also reduced the age structure of the forests and created excellent habitat for moose whilst forest reindeer seem to be one of many losers in the modified landscapes (Kojola et al. 2009) where diverse and untouched forests cover ever smaller fractions of the boreal forest belt.

##### 4.2. Carnivore predation

Whilst logging and clear-cutting has created suitable pasturelands for moose, the increase in the number of large carnivores is considered a key reason for reindeer declines in eastern Finland. Brown bear (*Ursus arctos*) mainly prey on calves in spring and early summer, while lynx (*Lynx lynx*) concentrate on hinds and one-year old calves. Kojola has shown that juvenile mortality among forest reindeer is twice as high in areas with dense wolf (*Canis lupus*) populations as in areas where wolves are rare, and that there is clear correlation between extended large carnivores

density and reindeer decline in the Kuhmo area (Kojola et al. 2009; Karlsson 2009; Kojola 2011). Because of its lower reproductive potential, forest reindeer are more impacted by predation than are moose.

##### 4.3. Traffic accidents

The risk of traffic accidents is high if spring and fall migration routes traverse busy roads (Figure 2). Car accidents seldom lead to human fatalities, but accidents are more frequent than in the past. As forest reindeer populations expand and yearly migration routes between feeding grounds become longer, animals will cross roads and railway lines more frequently than in the past.

Figure 2. The risk of traffic accidents is increasing in vicinity of busy roads.

#### 4.4. Poaching

Individual cases of poaching have occasionally been reported from Finland, although they are rare. In western Russia, poaching is one of the most serious obstacles restricting the subspecies' recovery (Sirkka 2015). In early spring, large herds stay in the vicinity of lakes and often become targets of illegal hunting. In winter, forest reindeer prefer to gather on frozen lakes where they are easy targets for hunting from snowmobiles. Illegal hunting from Russia is also reported in summer when animals swim between the mainland and islands (Karelia ENPI CBC Programme project 2013-2014).

An evident lack of guards in Russia makes monitoring difficult. As roughly one-third of the animals in Eastern Finland regularly cross the border zone, illegal poaching in Russia negatively affects the Finnish population. Although only five to six illegal killings are reported annually in Russia, local residents claim that the actual number is significantly higher. A large number of local inhabitants seem to be ignorant of the subspecies' status, and so to promote its protection in Russian Karelia, the Russian-Finnish Wild Forest Reindeer Project has produced pamphlets and information sheets to be distributed among schoolchildren and local residents (<https://www.suomenpeura.fi/en/population-management/karelia-enpi-cbc-programme-project-2013-2014.html>).

#### 5. Conservation activities in Finland: LIFE

#### Project supports on-site breeding and new reintroductions/re-stockings

To interrupt the decreasing population trends in eastern Finland and to

expand the current distribution, new populations will be established through on-site breeding and reintroductions (Blomqvist & Mykrä 2017; Blomqvist 2018), actions that were already recommended in the Finnish management plan for wild forest reindeer (Ministry of Agriculture & Forestry 2007). Experiences from previous reintroductions in the 1980s will be used in the project. Two national parks in SW Finland, Seitsemisen and Lauhanvuori, have been selected as new reintroduction sites (Figure 3). The two national parks, 45 and 53km<sup>2</sup> in size, located 60km apart, have been selected mainly because of their suitable biotopes with lichen heaths and marshes, but also because of their lower carnivore densities compared to eastern Finland. Two on-site breeding enclosures of 14 and 31 hectares have been built in the national parks (Figure 4). Breeding females have been donated from participating EAZA zoos: Ähtäri, Ranua, Helsinki and Nordens Ark (Blomqvist 2018). A six hectare large "transit" enclosure for collecting individuals that will be used for re-stocking the fragmented population in the Karstula-Ähtäri-area was also built in the Aittosuo Natural Reserve in 2018.

The reintroduction sites are located in two Natura2000 areas that were inhabited by forest reindeer two centuries ago. In the years to come, it is hoped that the reintroduced animals will merge and blend with the core population in central Finland, thus advancing the expansion of forest reindeer in the country. If the project proves successful, the new reintroduction sites might serve as future core areas for wild reindeer, facilitating the subspecies in reclaiming its historical range in the south-western parts of the country. As the scientific name refers to, *R.t. fennicus* has a strong symbolic value for Finland as part of the country's cultural heritage and it has been assumed that Finland was partly inhabited by people following this important game species northwards (Hulkko 2011). The reintroduction effects are expected to bring strong media coverage to both national parks and promote tourism in the areas (Hiedanpää & Pellikka 2013). The reintroduced subpopulation in Suomenselkä has proved to be a prominent tourist attraction, and the planned actions could have a positive effect on the attractiveness of the national parks in Seitsemisen and Lauhanvuori. After breeding in the on-site enclosures, the wild-caught animals will be transferred to the captive stock to diversify the gene composition of the captive population.

The project is coordinated by Wildlife Service Finland, with nine collaborating partners ([LIFE15 NAT/FI/000881](https://lifeprojects.eu/life15/nat/fi/000881)).

The budget for the LIFE project is estimated at €5.16 million, 60% of which will be provided by the EU, while the remainder will be financed by the Finnish state, the Finnish Hunters' Association, plus a number of collaborating

Figure 4. On-site breeding enclosure at Lauhanvuori NP. Photo: Milla Niemi, Metsähallitus

and supporting stakeholders, including EAZA. The reintroduction costs are estimated at €1 million. The majority of the funding is allocated towards habitat restoration, studies on habitat requirements, landscape utilization of the released animals and measures to reduce traffic mortality. To facilitate field censuses, more than 100 individuals will be equipped with satellite collars.

### 5.1. New founders incorporated to improve gene pool

Gene diversity (GD) is vital to all animals for their evolution. The primary goal of the breeding programme is to also maintain a demographically robust *ex situ* population that is genetically representative of its wild counterparts and to sustain these characteristics for the foreseeable future. Sufficient levels of GD must therefore be retained to allow the captive population to adapt to a variety of future environmental conditions (Blomqvist & Sliwa 2016). Forest reindeer are currently exhibited in 25 European zoo collections, three of which are non-EAZA members (Lauhanvuori National Park, Seitsemisen National Park and Zapovednik Kerzhensky in Russia).

It is known that the more founders a population descends from, the better its prospects for future generations. Isolated populations lose part of their GD with each successive generation, and the loss of alleles has eroded the level of GD during the decades reindeer have been maintained in captivity. Prior to 2018, the captive stock descended from only eight founders, the last one of which was brought to Ähtäri Zoo in 2004. An effective way to expand the gene pool is to incorporate new founders at regular intervals (Lees & Wilcken 2013) and periodic supplementation of wild-caught animals has been a priority issue for the programme. To enrich GD, not only among the animals that will be released, but also among the animals kept in captivity, two males

and a pregnant female were captured in Kainuu in eastern Finland in 2017 and transferred to the breeding enclosures in Seitsemisen and Lauhanvuori National Parks (Blomqvist 2018). The wild-caught individuals have been mixed with 10 captive-bred females (Figure 5) in the two enclosures where breeding will continue until 2022, with reintroductions starting in 2019 and ending in 2023.

The native zoos of Ähtäri, Helsinki and Ranua have agreed to provide the on-site facilities with fawns each year for as long as breeding continues. In 2018, five calves were born in the two facilities and at the end of the year, 21 individuals were kept in the on-site enclosure in the two national parks (Table 1).

Figure 5. Captive-bred females have been mixed with wild-caught individuals in the on-site breeding enclosures in the two national parks. Photo: Milla Niemi, Metsähallitus

After breeding in Lauhanvuori and Seitseminen in 2018-19, the wild-caught stags were transferred to the zoos in Ähtäri and Ranua where they hopefully will spread their genomes to the captive population. In 2019, the breeding males were replaced with two new potential founders caught in central Finland. In March 2019, an additional wild-caught hind and her female calf from the core population in Eastern Finland were also caught and transferred to the breeding herd in Lauhanvuori National Park.

Incorporation of new founders into the captive population enables an establishment of a Finnish zoo population that represents a reservoir of genetically distinct individuals, the offspring of which can be transferred to foreign zoos to reduce inbreeding in the European *ex situ* population. The captive population can subsequently function as a nucleus to produce and prepare individuals for further supplementations and reintroductions if new conservation strategies will become necessary for forest reindeer in Fennoscandia.

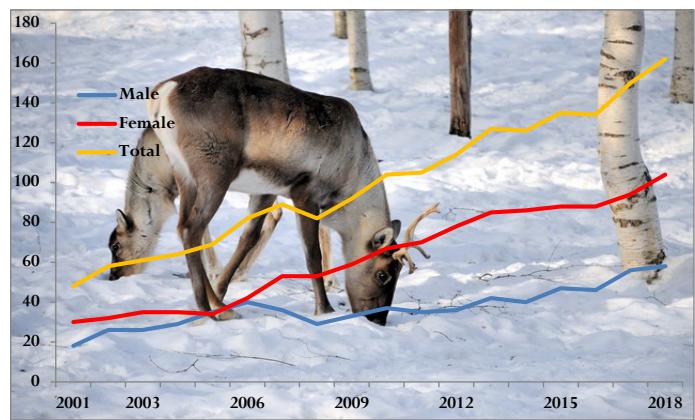

Figure 6. Census of *ex situ* population 2001-2018

## 6. The *ex situ* population

### 6.1. Main events in 2018

The total number of animals in the captive population increased by 12 individuals from 150 animals in 2017 to 162 in 2018 (Figure 6). The main events during the year are summarized in Table 1, showing that 49 calves (25.24)

were born, 33% (10.6) of which died within half a year. The total of deceased individuals was 31 (17.14) head, while 18 (12.6) reindeer were transferred between the participating institutions in the programme. As planned, the free-living subpopulation in the Karstula-Ähtäri area will be supplemented with captive-bred individuals and in 2018, six captive-bred stags were transferred to the transit enclosure in Aittasuo Nature Reserve for release in spring 2019.

As Magdeburg left the ESB whilst Han-sur-Lesse joined the programme during 2018, the number of participating institutions remained at 25 institutions. An encouraging sign is that three zoos - Opel Zoo (Kronberg), Reservé d'Animaux Sauvage (Han-sur-Lesse) and Augsburg - have agreed to keep bachelor herds. Although females represent the main reproductive unit in a population, the genomes of both sexes are equally important, particularly in polygamous species where dominant stags monopolize breeding of multiple hinds. The establishment of bachelor herds where stags can temporarily be maintained for exhibit until moved into breeding situations elsewhere is consequently beneficial for the breeding programme.

Additional holders are encouraged to keep backup groups of stags that can be rotated for breeding among participating holders. Four additional zoos have showed interest in surplus animals and have signed up for participation in 2019-2020 when animals will become available.

## 6.2. Demographic overhaul of the ESB population

The aim of the breeding programme is to establish a healthy population of forest reindeer in European zoos by promoting the use of good management practices to maintain a sustainable and jointly managed *ex situ* population that can contribute to viable populations in the wild. Since the establishment of the breeding programme, the studbook population has grown from 48 (18.30) animals in 2001 to 162 (58.104) individuals at the end of 2018 (Figure 6). Figure 7 shows that this favourable population development has been a result of captive births exceeding the number lost animals during 2001-2018. In the last five years, the captive population has exhibited an average yearly growth rate of 6.5% (average  $\lambda$  of 1.065).

Figure 7. Number of captive births/ deaths 2001-2018

Figure 8. Time of delivery. Figure based on 683 birth events 1980-2018

## 6.3. Fecundity

Forest reindeer are seasonal breeders and all recorded births have taken place from late April until mid-August, with a peak in May when 77% of all calves have been delivered (Figure 8). In captive conditions both sexes start to reproduce during the third year and females continue to give birth until the age of 13 when fecundity sharply drops (Figure 9). The oldest captive-bred female to have given birth was 15 years when she delivered her last calf. In captive conditions, stags have a shorter reproductive period than do females and the oldest male of known age to have sired a calf was 13 years and four months. It is worth mentioning, however, that the shorter fecundity in stags does not reflect their biological potential, but rather indicates the results of management practices utilized to avoid inbreeding, where males are rotated out of breeding situations after a short time. Among free-roaming forest reindeer, young stags unlikely have opportunities to mate when younger than two years.

Forest reindeer have a low reproductive potential and among the 683 calves that have been born, only one twin birth has been recorded. On this occasion, only one of the twins survived while the other was delivered stillborn (personal communication from Helsinki Zoo). Twin calves are also extremely rare in free-ranging populations (*Bisi & Härkönen 2017*).

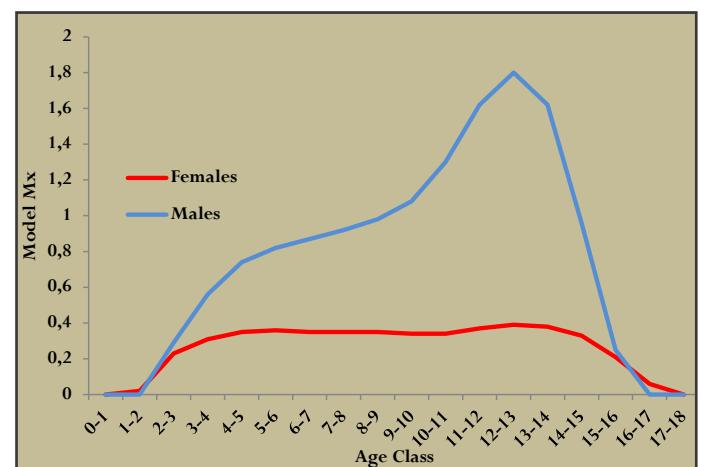

Figure 9. Age specific fecundity ( $M_x$ ) calculated out of 634 birth events prior to 1.1. 2019

#### 6.4. Mortality

Data of 501 death events for captive-born animals in the studbook reveals that the first six months are crucial for reindeer calves - there is a 34% chance that the calf will not survive its first year of life. Figure 10 illustrates that mortality drops after the first year and both sexes can live for more than ten years. The oldest captive-born stag lived for fourteen years and five months while the oldest female lived sixteen years and one month. In the current population, the oldest stag is twelve years and six months old, whereas the oldest hind is twelve years and seven months old. After eight years of age, mortality slowly starts to increase in both sexes and accelerates after age of ten.

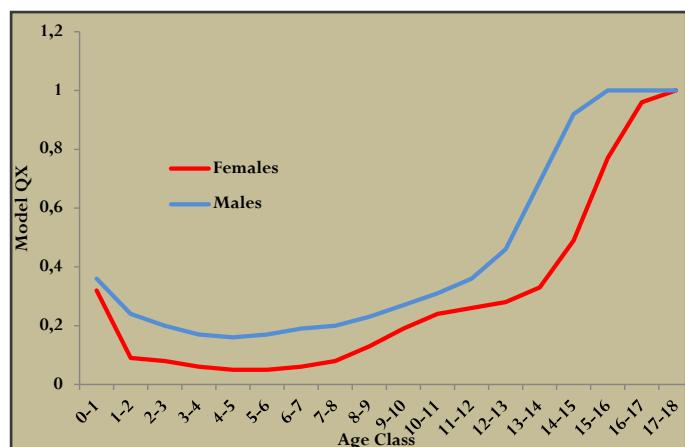

Figure 10. Age specific mortality ( $Q_x$ ) calculated out of 501 death events prior to 1.1.2019

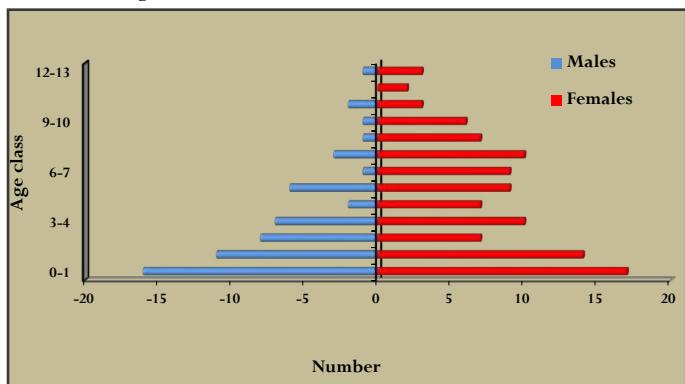

Figure 11. Age/sex pyramid in captive population as of 1.1.2019

The age structure of the studbook population is fairly stable, with a sex ratio skewed towards females (Figure 11) as can be expected in a polygamous species. Particularly during the last five years, the population has grown rapidly with an average of 42 births and 34 deaths each year (Figure 7). According to the current growth rate, the population will grow to about 250 individuals in the next few years. Worth remembering is, however, that all captive-bred animals in the two national parks will be used for reintroductions/re-stockings and the increase will therefore be significantly smaller than projected.

#### 6.5. Genetic summary of the 2018 population

A critical factor in managing small populations is the number of founders from which the population descends. Twenty to 30 founders are recommended as the minimum number needed to maintain a long-term sustainable population (*Leus*

*2011; Leus et al. 2011*). Table 2 shows that although 20 wild-caught forest reindeer were brought into captivity, only eleven reproduced. Lack of breeding success among the 4.5 wild-caught individuals that did not reproduce may depend on a variety of reasons such as unsuccessful management in the past, advanced age or poor health status. Also, many founders that do breed may only have a few calves that themselves do not reproduce well and therefore show only a marginally visible representation in the current population. The disproportionate breeding results among the founders and their descendants is illustrated in Figure 12, showing a highly skewed contribution where one stag alone has contributed to half of the population's gene pool. Needless to say, populations with unequal founder representations contain less GD than populations with the same number of founders but where these have contributed more equally to future generations (*Lacy 1989*). Such a disproportionate founder contribution is common not only among a number of *ex situ* populations, but can also be found in the wild where the fittest individuals tend to produce more offspring.

The 11 wild-caught reindeer that have bred constitute the founder base in the existing *ex situ* population. Three wild-caught animals were alive in the collection in 2018. Thanks to the successful propagation of two of these in 2018, the number of founders increased from eight to 11 with one additional potential founder still living. Table 2 also shows that among the living animals, 16 stags and 57 hinds have reproduced at least once. A common misapprehension is that the number of living breeders corresponds to the effective population size ( $N_e$ ). This is not the case - the effective population size can be calculated by using the equation:

$$N_e = 4 \times (M \times F) / M + F$$

where  $M$  = is the number of current breeding males and  $F$  = the number of current breeding females. Accordingly,  $N_e$  is not the number of currently reproducing individuals (73) in the population but de facto 42.5 (Table 3), representing 26% of the entire population. The ratio of  $N_e$  to  $N$  is thus a good indicator of the demographic and genetic health status of the population, informing the rate at which gene diversity is lost. The effective population size is normally substantially smaller than the actual population size ( $N$ ) of 162 animals. Polygamous species where a dominant male controls

Table 2. Extracted data from studbook 1.1.2019.

breeding, further decreases Ne. The smaller Ne is, the more GD has been lost. In wild populations, the ratio of Ne/N is reported to lie at approximately 0.1 (*Frankham 1995*), whereas captive populations mostly have a Ne/N ratio that is larger than in the wild and ranges from 0.2 to 0.4 (*Frankham et al. 2002; Mace 1986*). In the forest reindeer studbook population, the Ne/N ratio of 0.26 (Table 3) falls within the range common to several captive populations (*Mace 1986*).

The amount of gene diversity is also linked to the numbers of individuals in the population and when the number of animals drops, GD declines. When a large number of animals breed, their cumulative genetic contribution will be passed on to the following generations allowing the population to better retain GD over time (*Long et al. 2011*). The current GD in the population is 85%, well below the ideal value of 90% or higher (*Tetzloff 2016*).

Because of bottleneck effects and the uneven reproductive success among the founders, the population has lost 15% of its GD during the 46 years reindeer have been managed in captive conditions. The current stock of 162 individuals thus displays the same amount of GD one finds among roughly three wild-born individuals ( $F_{ge} = 3.27$ ). The most important event in 2018 was therefore without doubt the successful propagation of a pair of potential founders, the hind of which had been covered by a wild stag before she was captured. Further breeding with these new wild-born animals is consequently a priority for the breeding programme.

Table 3 shows, that simulations with the software Population Management 2000 (*Pollak et al. 2002*) indicate that if the

<b>Mean inbreeding coefficient (F)</b>	0.127	

Table 3. Demographic and genetic summary of captive population 1.1.2019

existing wild-caught animals can be bred successfully, GD can be significantly increased from its current level of 84.7%. If the potential founders that arrived in 2019 also can be incorporated into the breeding pool, the gene composition can be further improved. The on-going LIFE project has enabled the establishment of a distinctive *ex situ* population in Finnish zoos that currently represents a reservoir of new founders, the offspring of which can be transferred to captive populations abroad to reduce the level of inbreeding. Captive-born animals can consequently function as a nucleus to prepare individuals also for new restocking and reintroduction attempts if this becomes a suitable conservation strategy for wild forest reindeer also in other parts of Fennoscandia.

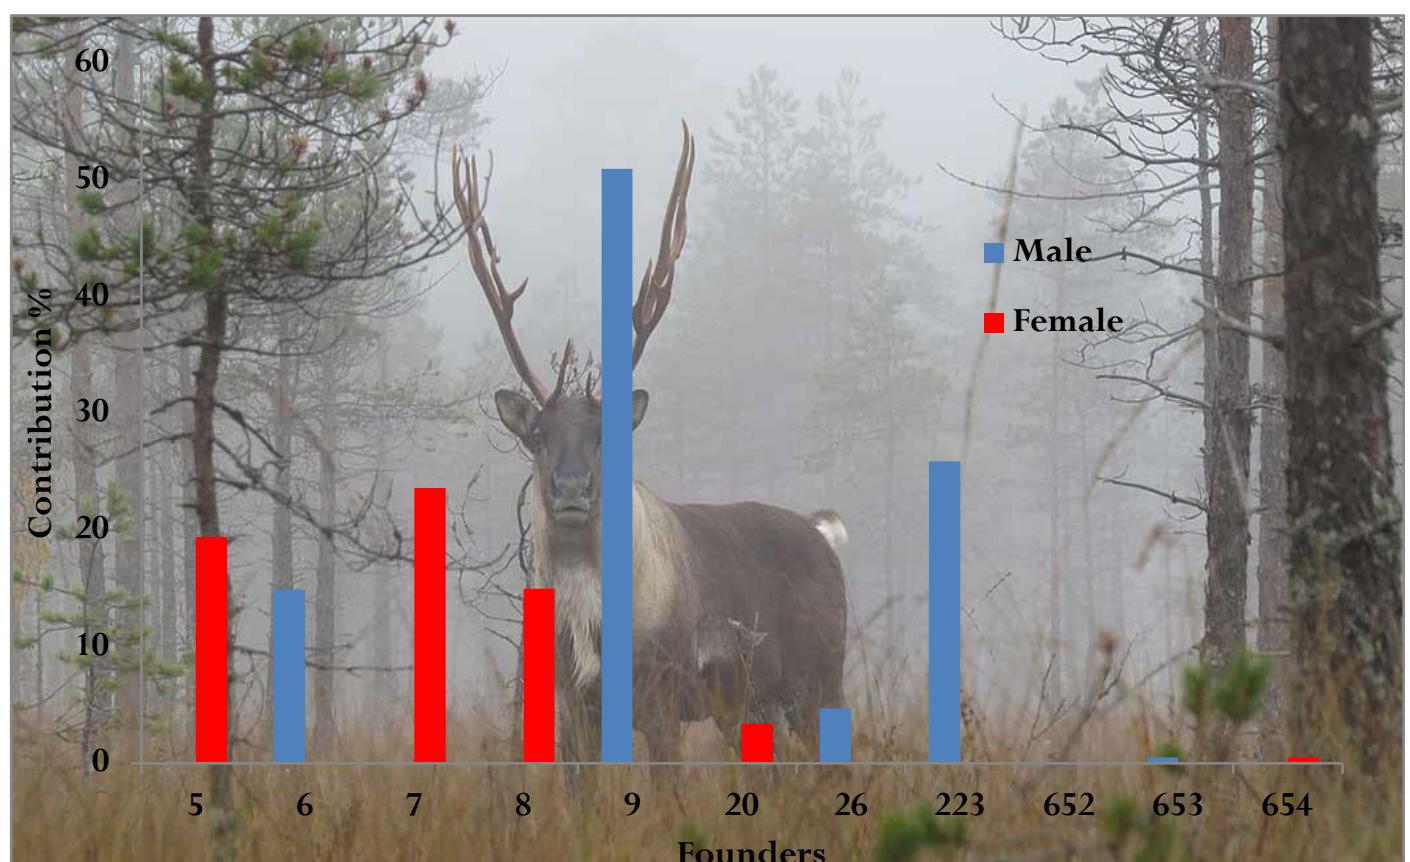

Figure 12. Founder contribution in *ex situ* population as of 1.1.2019
